# Algebraic analysis of discrete dynamical systems ACiD Seminar • 8 December 2020 

Antonio E. Porreca • aeporreca.org
Aix-Marseille Université \& LIS • Marseille, France

# Finite, discrete-time dynamical systems 

# Finite, discrete-time dynamical systems Just a finite set with a transition function $(A, f)$ 

## Finite, discrete-time dynamical systems

 Just a finite set with a transition function $(A, f)$ modulo isomorphism

## General shape of a dynamical system

A few limit cycles

## General shape of a dynamical system

A few limit cycles with trees going in

## General shape of a dynamical system

 A few limit cycles with trees going in
## General shape of a dynamical system

A few limit cycles with trees going in

## General shape of a dynamical system

A few limit cycles with trees going in

# Operations over dynamical systems 

## The inspiration

The category of endomaps of sets

Conceptual Mathematics
A first introduction to categories Second Edition
F. William Lawere Stephen H. Schanuel

## Sum of dynamical systems Necessary but not that interesting

- In graph-theoretic terms, it's just the disjoint union
$(A, f)+(B, g)=(A \uplus B, f+g) \quad$ with $(f+g)(x)= \begin{cases}f(x) & \text { if } x \in A \\ g(x) & \text { if } x \in B\end{cases}$
- This represents the alternative execution of $A$ and $B$
- The identity is the empty system $\mathbf{0}=(\varnothing, \varnothing)$

## General shape of a dynamical system

 It's a sum of cycles with trees going in

# Product of dynamical systems Now we're talking! 

- In graph-theoretic terms, it's the tensor product

$$
\begin{aligned}
& (A, f) \times(B, g)=(A \times B, f \times g) \\
& \text { with }(f \times g)(a, b)=(f(a), g(b))
\end{aligned}
$$

- This represents the synchronous execution of $A$ and $B$
- The identity is the singleton system $\mathbf{1}=(\{0\}, \mathrm{id})$

## Product in D is graph tensor product

 Two systems modulo isomorphism
$=$

## Product in D is graph tensor product

Temporary state names

## Product in D is graph tensor product

 Cartesian product of the states

## Product in D is graph tensor product

 Arrows iff arrows between both components

## Product in D is graph tensor product

 We forget the state names once again

# Introducing: the multiplication table, poster-size

## Prettier version

# The semiring $\mathbf{D}$ of dynamical systems 

## D (modulo isomorphisms) is a semiring Like a ring, without subtraction

- Product is (modulo isomorphism) commutative, associative and has identity $\mathbf{1}=(\{0\}, i d)$; so, it's a commutative monoid
- Sum is (modulo isomorphism) commutative, associative and has identity $\mathbf{0}=(\varnothing, \varnothing)$; so, another commutative monoid
- The sum is the free commutative monoid (i.e., the multisets) over the set of connected, nonempty dynamical systems
- We also have a distributive law and the product annihilation law

## Motivation <br> Exploit algebra to decompose large systems

- Many decision problems on dynamical systems are intractable
- We try to make them "less intractable" by reducing the size
- We can deduce certain dynamical properties of complex systems in terms of the dynamics of its components
- The fixed points of $A+B$ are those of $A$ and those of $B$
- The fixed points of $A \times B$ are pairs of fixed points of $A$ and $B$
- We can also compute number and lengths of cycles this way

No unique factorisation!

## Multiplication table

| 0 | $\varnothing$ |  |  |  |  |  |  |

## No unique factorisation <br> And the counterexample is minuscule

- The systems $C_{!} C_{0}$ and $\square_{0}$ are irreducible
- Any system with a prime number of states is irreducible, since the state space is a cartesian product
- So . ${ }_{.}^{\text {. }}$. 0 has two distinct factorisations into irreducibles

# Systems with arbitrarily many factorisations 

## Theorem

For each $n$, there exist a dynamical system with at least $n$ factorisations

## Theorem

For each $n$, there exist a dynamical system with at least $n$ factorisations

## Theorem

For each $n$, there exist a dynamical system with at least $n$ factorisations

$$
(\zeta)^{n}=\Omega_{\Omega} \times(\delta \Omega)^{n-1}
$$

## Theorem

For each $n$, there exist a dynamical system with at least $n$ factorisations

$$
\begin{aligned}
(\delta)^{n} & =\Omega_{\Omega} \times(\delta \Omega)^{n-1} \\
& =\left(\Omega_{\Omega}\right)^{2} \times(\delta \Omega)^{n-2}
\end{aligned}
$$

## Theorem

For each $n$, there exist a dynamical system with at least $n$ factorisations

$$
\begin{aligned}
(\delta))^{n} & =\Omega_{\Omega} \times(\delta \Omega)^{n-1} \\
& \left.=\left(\Omega_{\Omega}\right)^{2} \times(\delta)\right)^{n-2} \\
=\cdots & =\left(\Omega_{\Omega}\right)^{n-1} \times \delta
\end{aligned}
$$

A notable subsemiring

## $\mathbb{N}$ is a subsemiring of $\mathbf{D}$

## This means trouble

- $\mathbb{N}$ is initial in the category of semirings
- Meaning that there is only one homomorphism $\varphi: \mathbb{N} \rightarrow \mathbf{D}$

$$
\varphi(n)=\underbrace{1+1+\cdots+1}_{n \text { times }}=\underbrace{C_{\bullet}+C_{\bullet}+\cdots+C_{\bullet}}_{n \text { times }}
$$

- In the case of $\mathbf{D}$, the homomorphism is injective, since $(\mathbf{D},+)$ is the free monoid over connected, nonempty dynamical systems
- So $\mathbf{D}$ contains a isomorphic copy of $\mathbb{N}$

A bit more algebra, of the linear kind

## D is a $\mathbb{N}$-semimodule <br> Like a vector space, but over a semiring

- Here the vectors are dynamical systems and the scalars are naturals
- Trivial because the semimodule axioms are a consequence of $\mathbb{N}$ being a subsemiring of $\mathbf{D}$ :

$$
\begin{aligned}
& n(A+B)=n A+n B \quad(m+n) A=m A+n A \\
& (m n) A=m(n A) \quad 1 A=A \quad 0 A=n \mathbf{0}=\mathbf{0}
\end{aligned}
$$

- D as a semimodule has a unique, countably infinite basis consisting of all nonempty, connected dynamical systems
- The fact that $\mathbf{D}$ is a semimodule will be useful later

Irreducible systems

## Most dynamical systems are irreducible

$A$ is irreducible iff $A=B C$ implies $B=1$ or $C=1$

- Formally: $\lim _{n \rightarrow \infty} \frac{\text { number of reducible systems over } \leq n \text { states }}{\text { total number of systems over } \leq n \text { states }}=0$
- The total number of systems over exactly $n$ states is asymptotically $\eta \frac{\alpha^{n}}{\sqrt{n}}$, with $\eta \approx 0.443$ and $\alpha \approx 2.956$
- A reducible system over $n$ states is the product of two systems with $p$ and $q$ states such that $p q=n$
- With a few summations and upper bounds, we get the result
- Notice that this is the opposite of the subsemiring $\mathbb{N}$

# Polynomial equations $\operatorname{over} \mathbf{D}\left[X_{1}, \ldots, X_{m}\right]$ 

## Polynomial equations over $\mathbf{D}\left[X_{1}, \ldots, X_{m}\right]$

 For the analysis of complex systems- Consider the equation

- There is least one solution

$$
x=6
$$

## Polynomial equations in semirings As opposed to rings

- A ring has additive inverses (aka, it has subtraction)
- Each polynomial equation in a ring can be written as $p(\vec{X})=0$
- This is not the case for our semiring, which has no subtraction
- The general polynomial equation has the form $p(\vec{X})=q(\vec{X})$ with two polynomials $p, q \in \mathbf{D}[\vec{X}]$

## Solvability of polynomial equations over D is undecidable

## Undecidability of polynomial equations <br> The spectre of Hilbert's 10th problem is haunting D

- We have showed that $\mathbb{N}$ is a subsemiring of $\mathbf{D}$
- But sometimes enlarging the solution space makes the problem actually easier: given $p, q \in \mathbb{N}[\vec{X}]$
- Finding if $p(\vec{X})=q(\vec{X})$ has solution in $\mathbb{N}$ is undecidable
- Finding if $p(\vec{X})=q(\vec{X})$ has solution in $\mathbb{R}$ is decidable
- Finding if $p(\vec{X})=q(\vec{X})$ has solution in $\mathbb{C}$ is trivial
- So, what about finding solutions in $\mathbf{D}$ ?

# Natural polynomial equations With non-natural solutions 

- Let $p(X, Y)=2 X^{2}$ and $q(X, Y)=3 Y$ with $p, q \in \mathbb{N}[X, Y] \leq \mathbf{D}[X, Y]$
- Then $2 X^{2}=3 Y$ has the non-natural solution

$$
X=Y=2
$$

- But, of course, it also has the natural solution $X^{\prime}=3, Y^{\prime}=6$
- Notice how $X^{\prime}=|X|$ and $Y^{\prime}=|Y|$
- This is not a coincidence!

# The function "size" $|\cdot|: \mathbf{D} \rightarrow \mathbb{N}$ It's a semiring homomorphism 

- $|\varnothing|=0$
- $|\Omega|=1$
- Since + is the disjoint union, we have

$$
|A+B|=|A|+|B|
$$

- Since $\times$ is the cartesian product, we have

$$
|A B|=|A| \times|B|
$$

# Notation for polynomials $p \in \mathbf{D}[\vec{X}]$ 

 Of degree $\leq d$ over the variables $\vec{X}=\left(X_{1}, \ldots, X_{k}\right)$

# Notation for polynomials $p \in \mathbf{D}[\vec{X}]$ 

 Of degree $\leq d$ over the variables $\vec{X}=\left(X_{1}, \ldots, X_{k}\right)$$$
\begin{aligned}
& p=\sum_{\vec{i} \in\{0, \ldots, d\}^{k}} a_{\vec{i}} \overrightarrow{X^{i}} \\
& \text { where } \quad \vec{X}^{\vec{i}}=\prod_{j=1}^{k} X_{j}^{i_{j}}
\end{aligned}
$$

for instance $(X, Y, Z)^{(2,4,3)}=X^{2} Y^{4} Z^{3}$

## Theorem

## Solvability of natural equations

- If a polynomial equation over $\mathbb{N}\left[X_{1}, \ldots, X_{k}\right]$ has a solution in $\mathbf{D}^{k}$, then it also has a solution in $\mathbb{N}^{k}$
- In the larger semiring $\mathbf{D}$ we may find extra solutions, but only if the equation is already solvable over the naturals
- Then, by reduction from Hilbert's 10th problem, we obtain the undecidability in $\mathbf{D}$ of equations over $\mathbb{N}[\vec{X}] \ldots$
- ...and thus of arbitrary equations over $\mathbf{D}[\vec{X}]$

## Proof

Consider $p(\vec{X})=q(\vec{X})$ with $p, q \in \mathbb{N}[\vec{X}]$

$$
\sum_{\{0, \ldots, d\}^{k}} a_{\vec{i}} \vec{X}^{\vec{i}}=\sum_{i \in\{0, \ldots, d\}^{k}} b_{\vec{i}} \overrightarrow{X^{\vec{i}}}
$$

## Proof

Suppose that $\vec{A} \in \mathbf{D}^{k}$ is a solution

$$
\sum_{\{0, \ldots, d\}^{k}} a_{\vec{i}} \overrightarrow{A^{i}}=\sum_{i \in\{0, \ldots, d\}^{k}} b_{\vec{i}} \overrightarrow{A^{\vec{i}}}
$$

## Proof

Apply the size function |•|

$$
\left|\sum_{i \in\{0, \ldots, d\}^{k}} a_{\vec{i}} \vec{A} \vec{i}\right|=\left|\sum_{i \in\{0, \ldots, d\}^{k}} b_{\vec{i}} \vec{A} \vec{i}\right|
$$

## Proof

The size function $|\cdot|$ is a homomorphism

$$
\sum_{\left\{\{0, \ldots, d\}^{k}\right.}\left|a_{\vec{i}} \overrightarrow{A^{\vec{i}}}\right|=\sum_{i \in\{0, \ldots, d\}^{k}}\left|b_{\vec{i}} \overrightarrow{A^{i}}\right|
$$

## Proof

The size function $|\cdot|$ is a homomorphism

## Proof

The coefficients are natural

$$
\sum_{\{0, \ldots, d\}^{k}} a_{\vec{i}}\left|\overrightarrow{A^{i}}\right|=\sum_{i \in\{0, \ldots, d\}^{k}} b_{\vec{i}}\left|\overrightarrow{A^{i}}\right|
$$

## Proof

We have $\overrightarrow{A^{i}}=\prod_{j=1}^{k} A_{j}^{i_{j}}$

## Proof

The size function $|\cdot|$ is a homomorphism

## Proof

The size function $|\cdot|$ is a homomorphism

## Proof

So $|\vec{A}|=\left(\left|A_{1}\right|, \ldots,\left|A_{k}\right|\right)$ is also a solution, QED

$$
p\left(\left|A_{1}\right|, \ldots,\left|A_{k}\right|\right)=q\left(\left|A_{1}\right|, \ldots,\left|A_{k}\right|\right)
$$

# Equations with non-natural coefficients 

## Equations without natural solutions

## They do exist

- Consider, for instance

$$
X^{2}=Y+
$$

- This equation has solution

$$
X=
$$

- But there is no natural solution, because the RHS is non-natural and cannot be made natural by adding stuff

# Polynomial equations with constant RHS are decidable and in NP 

## Nondeterministic algorithm

 For $p(\vec{X})=C$ with $C \in \mathbf{D}$- Since + and $\times$ are monotonic wrt the sizes of the operands, each $X_{i}$ in a solution to the equation has size $\leq|C|$
- So it suffices to guess a dynamical system of size $\leq|C|$ for each variable in polynomial time, then calculate LHS
- Finally we check whether LHS and RHS are isomorphic, exploiting the fact that graph isomorphism is in NP
- Only one caveat: if at any time during the calculations the LHS becomes larger than $|C|$, we halt and reject (otherwise the algorithm might take exponential time)

Systems of linear equations with constant RHS are NP-complete

## NP-hardness of linear systems By reduction from One-in-three-3SAT

- Given a 3CNF Boolean formula $\varphi$, is there a satisfying assignment such that exactly one literal per clause is true?
- For each variable $x$ of $\varphi$ we have one equation $X+X^{\prime}=1$, forcing one between $X$ and $X^{\prime}$ to be 1 , and the other to be 0
- For each clause, for instance ( $x \vee \neg y \vee z$ ), we have one equation $X+Y^{\prime}+Z=1$, which forces exactly one variable to 1
- These are all linear, constant-RHS equations over $\mathbf{D}[\vec{X}]$ (actually $\mathbb{N}[\vec{X}]$ ), and its solutions are the same as the satisfying assignments of $\varphi$ with one true literal per clause

A single linear, constant-RHS equation is NP-complete

## Reducing the system of equations to one

## Several $\mathbb{N}[\vec{X}]$ linear equations to one $\mathbf{D}[\vec{X}]$ equation

- Let $p_{1}(\vec{X})=1, \ldots, p_{n}(\vec{X})=1$ be the previous system of equations, with $p_{i} \in \mathbb{N}[\vec{X}]$
- Recall that $\mathbf{D}$ is a $\mathbb{N}$-semimodule with basis all connected systems
- Take any $n$ easy-to-compute, linearly independent systems $e_{1}, \ldots e_{n} \in \mathbf{D}$, for instance

$$
e_{2}=
$$

$$
e_{3}=a_{0}
$$

- Then the equation $e_{1} p_{1}(\vec{X})+\cdots+e_{n} p_{n}(\vec{X})=e_{1}+\cdots+e_{n}$ is a linear equation over $\mathbf{D}[\vec{X}]$ having the same solutions as the original system

## Open problems

## Open problems

## Algebraic ones

- Are there prime elements $P$, that is, whenever $P$ divides $A B$ it divides either $A$ or $B$ ? What do they represent?
- We know exactly zero prime elements
- Does it make any sense to adjoin the additive inverses in order to obtain a ring?
- Think about imaginary numbers, using them in intermediary computation steps, but discarding any imaginary solutions
- Is it useful to find nondeterministic dynamical system (i.e., arbitrary graph) solutions to equations?
- Semirings of infinite discrete-time dynamical systems

## Open problems <br> Computability and complexity

- Find larger classes of solvable equations, e.g., by number of variables or degree of the polynomials
- Do we obtain the same results as for natural numbers?
- The semiring of computably infinite dynamical systems
- Discover classes of equations solvable efficiently
- Hard for systems in succinct form
- Find out if there exist decidable equations harder than NP
- It would feel strange to jump from NP to undecidable
