Computing (CMC16)*

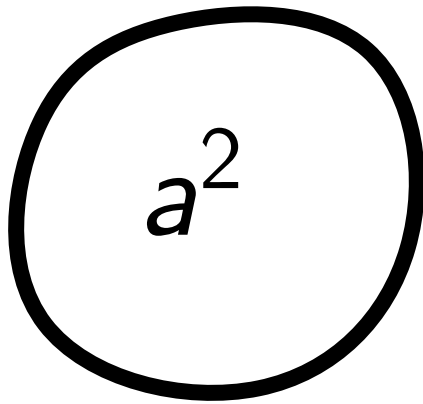

Objects with negative multiplicity

$$a^3 \rightarrow bc$$

When do we stop?

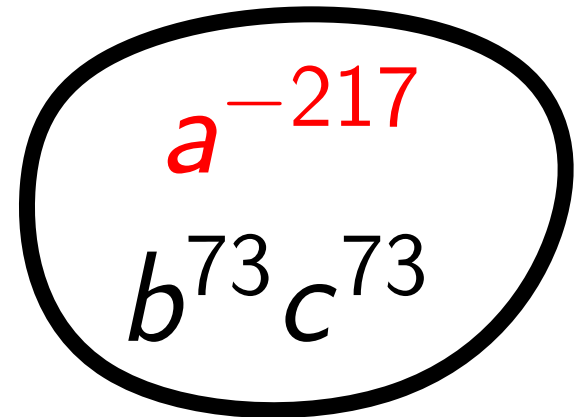

$$a^3 \rightarrow bc$$

A circle containing the expression a^2 .

73 applications
of the rule

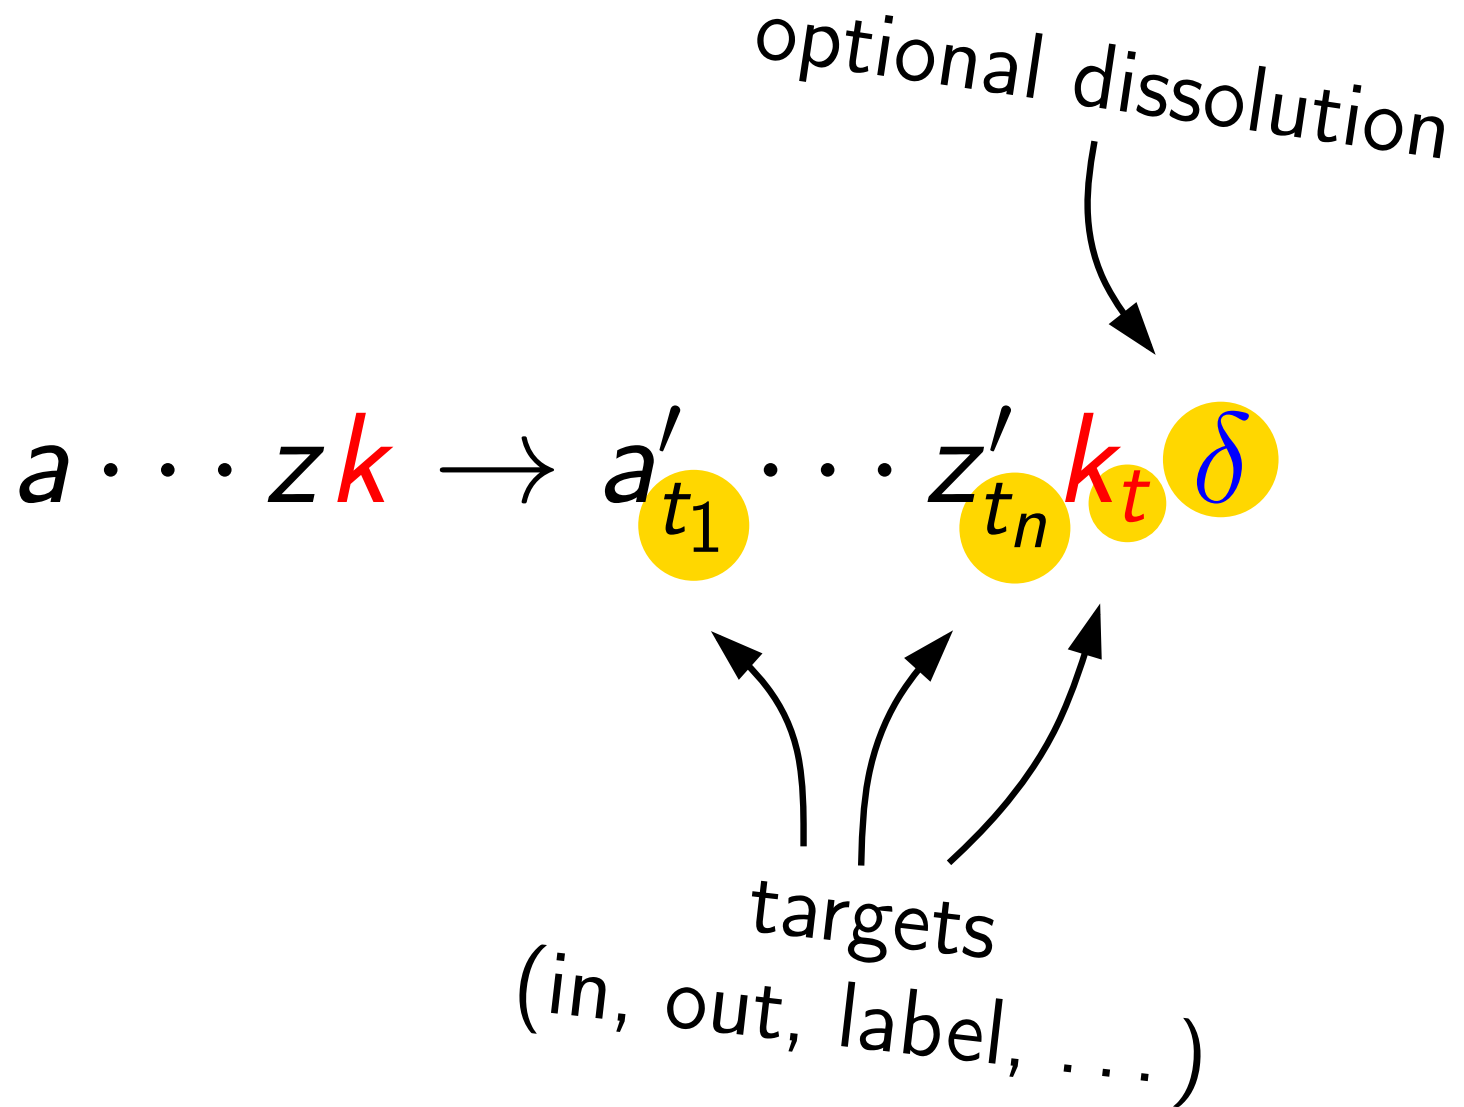

An oval containing the expression $a^{-217} b^{73} c^{73}$. The a^{-217} term is written in red.

Proposal: have (moving) catalyst objects

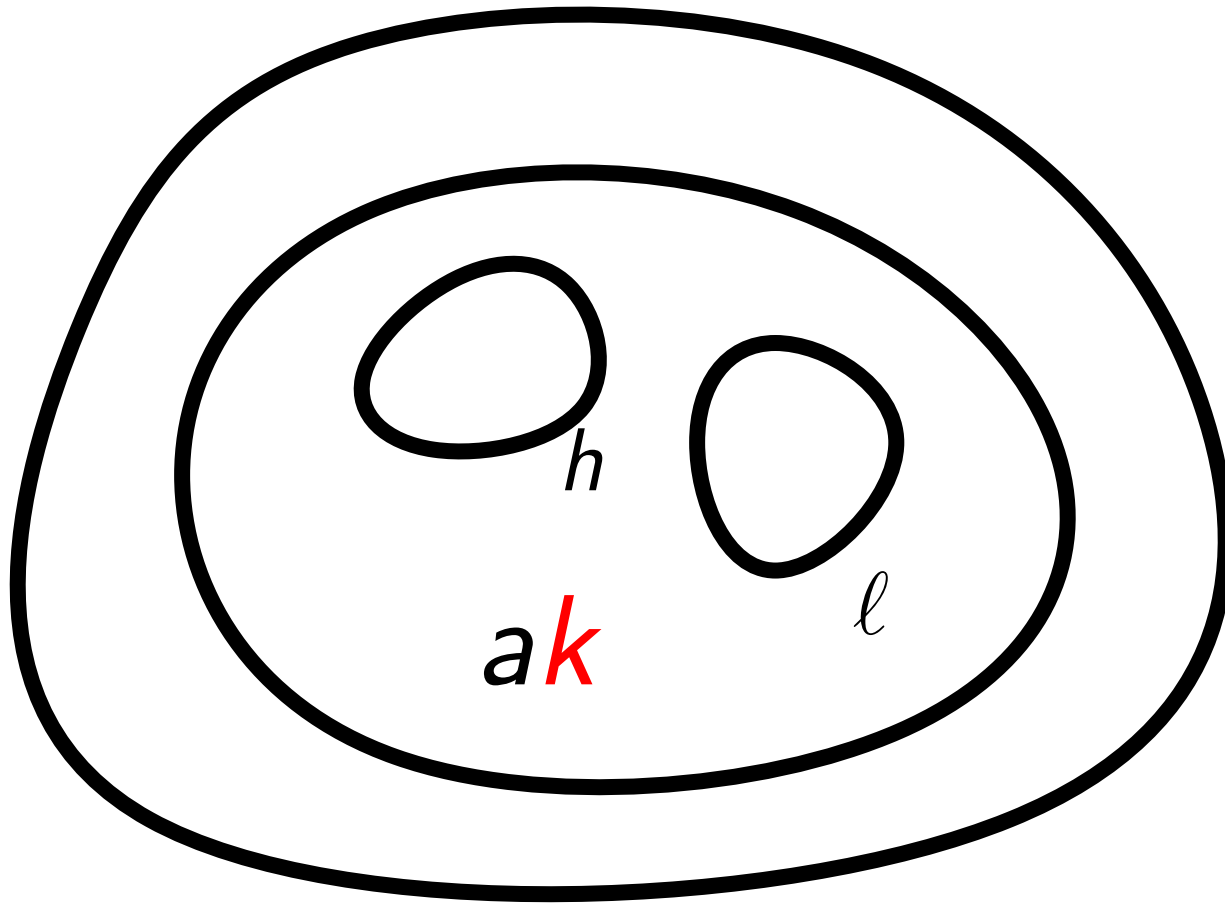

Catalysts obey mass conservation
and cannot have negative multiplicity

General rule form

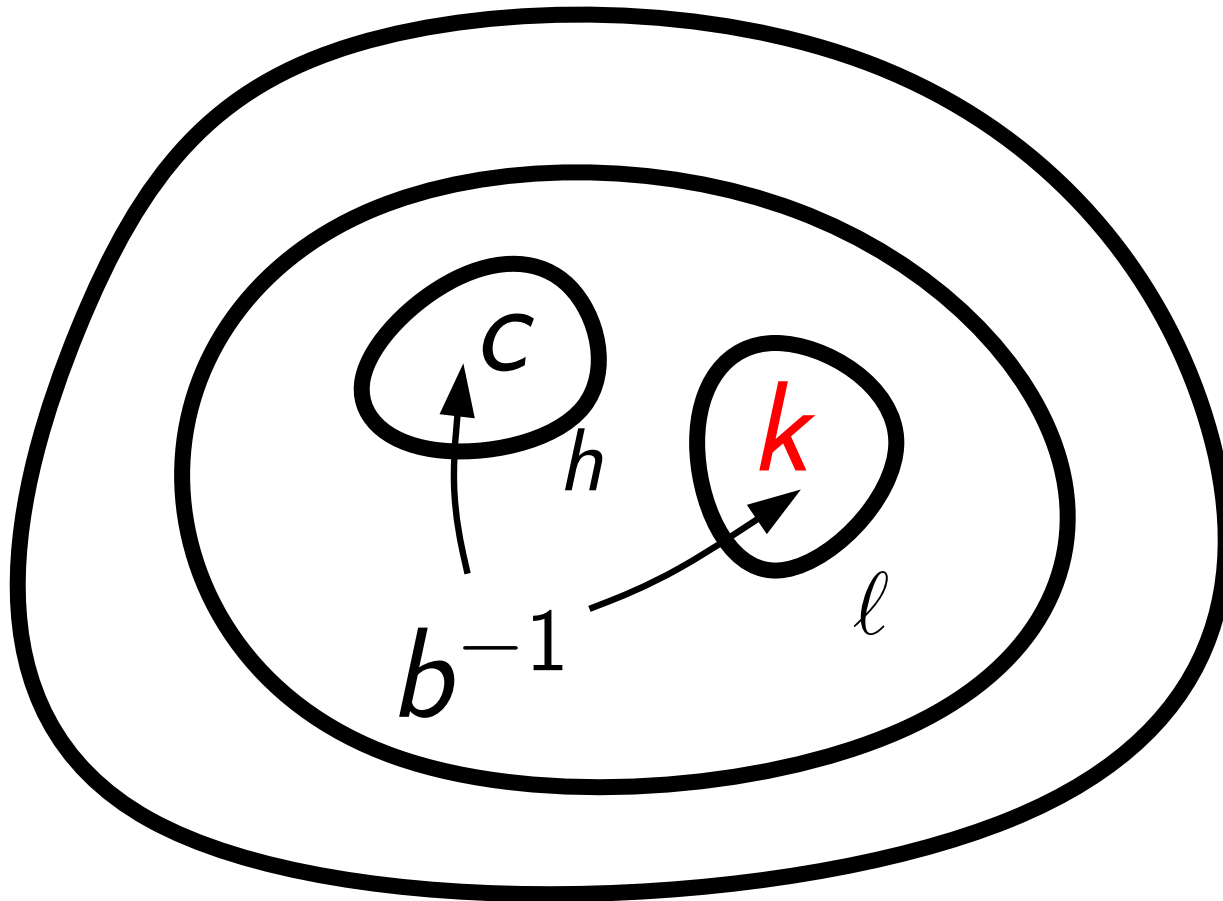

Example

$$abk \rightarrow c_h d_k k_\ell$$

Example

$$abk \rightarrow c_h k_\ell$$

Consequence: rules become context-free

$$uk \rightarrow vk$$

$$k \rightarrow vu^{-1}k$$

Register machines

$l_1 : \text{add}(r), l_2, l_3$

$l_1 : \text{sub}(r), l_2, l_3$

$l_1 : \text{halt}$

Consequence of using hybrid sets: no zero test

$l_1 : \text{add}(r), l_2, l_3$

$l_1 : \text{sub}(r), l_2, \text{abort}$

$l_1 : \text{halt}$

A subset of the registers must be null at the end of legitimate computations

Simulation by partially blind machines

- “positive” a 's in region 0
- “negative” a 's in region 0
- “positive” b 's in region 0
- “negative” b 's in region 0

⋮

“negative” z 's in region 2

~~registers for catalysts~~

output registers

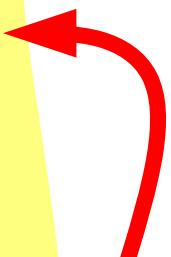

Simulation algorithm

*just look at
the catalysts*

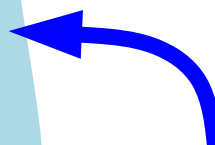

nondeterministically choose a multiset of rules to apply
for each chosen rule $uk \rightarrow vk$ with targets **do**
 add u to the corresponding “negative” registers
 add v to the corresponding “positive” registers
jump to the code for the new configuration of catalysts

*code for each
cfg of catalysts*

for each output symbol a **do**
 nondeterministically guess if $\#a$ is negative
 if we guessed negative **then**
 compute Δa in the negative output register
 else
 compute Δa in the positive output register

*except for
halting ones*

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a < 0$*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a < 0$*

*copy until empty
(just guess)*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a < 0$*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

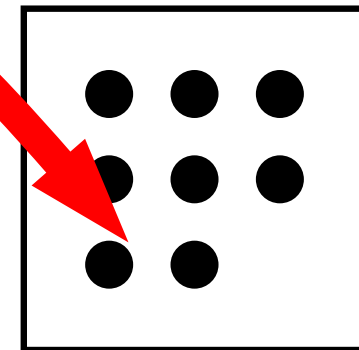

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a < 0$*

*now subtract
these ones*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a < 0$*

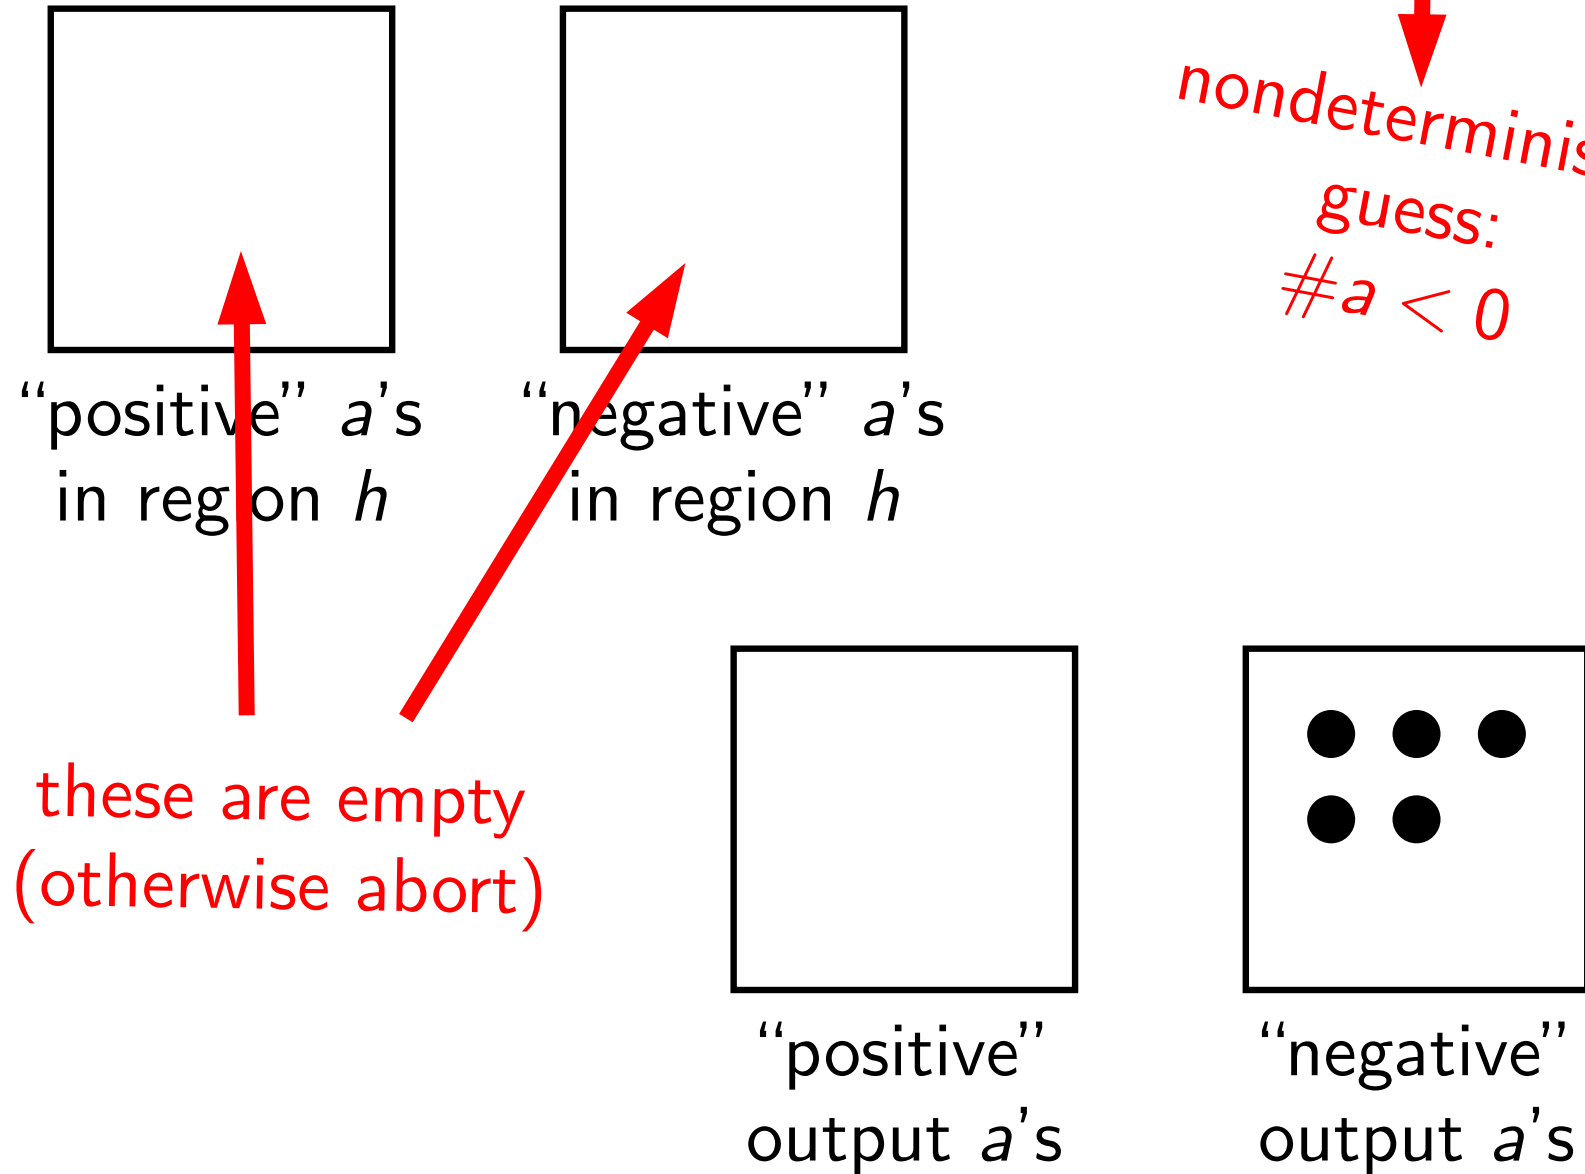

“positive”
output a 's

“negative”
output a 's

Computing Δa

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a \geq 0$*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a \geq 0$*

*copy until empty
(just guess)*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a \geq 0$*

“positive”
output a 's

“negative”
output a 's

Computing Δa

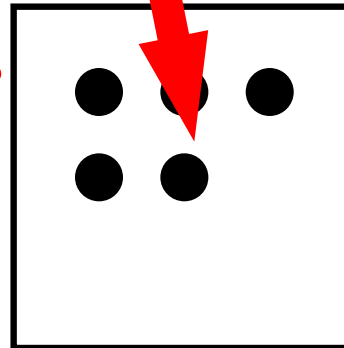

“positive” a 's
in region h

“negative” a 's
in region h

*nondeterministic
guess:
 $\#a \geq 0$*

*now subtract
these ones*

“positive”
output a 's

“negative”
output a 's

Computing Δa

“positive” a 's
in region h

“negative” a 's
in region h

wrong guess!

nondeterministic
guess:

$\#a \geq 0$

FAIL

“positive”
output a 's

“negative”
output a 's

Summary

Theorem. These kinds of P system can be simulated by a partially blind register machine, and so they are not universal □

Improvement (see papers at CMC17 in Milano)

Theorem. These kinds of P system can be simulated by a **blind** register machine, and so they are even less universal □
